# Homework 9&10: Creativity and Processing

**Goal:** The purpose of this exercise is to give you a chance to create, and to get experience writing simple Processing Programs to give practice with the language features.

In the assignment you will write four active Processing programs to display something of interest to you. These are not to be complex programs, but rather simple programs that do something cute or clever or interesting or have some other property that would interest a viewer. Below are four examples; notice that these are short programs that do something worth watching for a moment. That's what you're supposed to do.

# Examples

Here are four simple Processing programs like the kind expected in this assignment. You can use anything from these programs, but keep in mind that small changes from one of these programs is NOT creative ... it's derivative! Grading is based on creativity, good use of the language and your comments. All programs are available on the calendar page.

#### **Random Lines**

It's easy to use the random number generator, which we've seen before, to create cool patterns. Here is a program that draws batches of 10 random lines of either white or red, chosen at random. Notice that I can use the random function directly as an argument in the line() function.

```
/* Valentines Lines
int i:
                                       iteration variable
void setup( ){
 size(500, 500);
                                     // set canvas
                                     // pick black for the
 background(0);
  frameRate(5);
                                    // more fun to go slow
  strokeWeight(2);
                                     // wide lines better
void draw( ) {
 if (random(0,1) < 0.5) {
                                    // Pick a color
   stroke(255,255,255);
                                    // Which is white
  } else {
    stroke(255, 0,0);
                                    // Which is red
  for (i = 0; i < 10; i++) { // Do a batch of 10
    line(random(1,499), random(1, 499), random(1,499), random(1, 499));
```

#### Seattle Rain

Randomization is used in many places in computing ... for example, to simulate the physical phenomena. Let's "simulate" the Seattle rain. This program generates droplets

of a random size and one of two different (but very similar) random colors. The slow frame rate makes the action develop in kind of a hypnotic way, like Seattle rain.

```
/* Its raining in Seattle
int i:
                                      // iteration variable
float x;
                                      // size of droplet
void setup( ){
  size(500, 500);
                                     // set canvas
                                     // pick black for the app
  background(0);
  frameRate(5);
                                     // more fun to go slow
  fill(0);
}
void draw( ) {
                                   // dark or light drop?
  if (random(0,1) < 0.5) {
    stroke(180,180,255);
                                    // dark this time
  } else {
    stroke(200,200, 255);
                                    // it's lighter
  for (i = 0; i < 10; i++) {
   \times = random(10, 20);
                                      // how big should drop be
    ellipse(random(1,499), random(1, 499), x, x); // rain!
}
```

## **Programming A Heart Beat**

Processing comes with various ways to make shapes, and so it is very flexible. Here a heart has been drawn with a few basic shapes, and colored red. The program then turns down the red some, and then turns it back up again, making it look like it is beating.

```
/* The Heart Beat
float dir=-1;
                                       // direction of change
float tinto=255;
                                       // start out red
void setup( ){
 size(500, 500);
                                      // set canvas
 background(64);
                                      // pick gray for the a
 frameRate(15);
                                      // more fun to go slow
                                      // show not lines
 noStroke();
  fill(255,0,0);
                                      // start out pure red
}
void draw( ) {
 ellipse(200,250,100, 100);
                                         //piece together
 ellipse(300,250,100, 100);
                                         //a heart shape
 triangle(153, 270, 348, 270, 250, 400); //from basic shapes
 rect(240, 250, 20, 20);
  tinto=tinto+dir*5;
                                          //set a new color
  if (tinto < 180 ) {
                                          //is it too dark?
                                         //yes, start to lighten
   dir=1;
  }
  if (tinto > 255) {
                                         //is it full color
                                         //start to darken
   dir=-1;
 }
  fill(tinto,0,0);
                                          //set the color
```

## Walking Man

In this program a simple stick figure is animated to walk forward ... will he fall into the abyss?? Run it to find out. Notice that the body can be moved simply using our standard move-to-the-right techniques, but the legs must work differently. It's not complex, but it gives the idea of a stick man walking.

```
int walk=0;
                                       // Which leg steps
                                       // main body motion
int x=0;
int step! = 0;
                                       // left leg step
int stepr = 0;
                                       // right leg step
void setup( ){
 size(500, 500);
 frameRate(30);
 smooth();
 noFill();
 strokeWeight(3);
                                       // ticker line
void draw( ){
 background(0);
                                       // erase previous
                                       // land is yellow
 stroke(255,255,0);
                                       // land left of abys:
  line(50, 170, 302, 170);
                                      // left side of abys:
// right side of abyss
// right of abyss
  line(302, 170, 300, 300);
  line(333, 170, 450, 170);
  line(333, 170, 333, 300);
                                      // stick man is read
  stroke(255,0,0);
                                     // head
 ellipse(100+x, 100, 20, 20);
  line(100+x, 110, 100+x, 140);
                                      // body
                                      // left arm
  line(100+x, 125, 80+x, 110);
                                      // right arm
  line(100+x, 125, 120+x, 110);
  if (walk == 0) {
                                       // which leg is moving
   stepl = stepl + 2;
                                       // left, go faster
  } else {
   stepr = stepr + 2;
                                       // right, go faster
                                       // actually move left
  line(100+x, 140, 90+stepl, 170);
                                       // actually move right
  line(100+x, 140, 110+stepr, 170);
                                       // stride over with?
  if (abs(stepl-stepr) >= 15) {
   walk = 1-walk;
                                       // yes, switch legs
  }
                                       // move rest of body
 x=x+1;
```

**Assignment.** Write four programs to do whatever you want (but don't copy the examples above), and try to make them clever or interesting or cute or have some property that would interest a viewer. You should try to use the topics that are covered in on or before Lecture 8, because those are the basics and one goal of this assignment is to practice the basics. But, if you need some other feature of processing that you find in the reference page, go ahead and use it. The goal is creativity ... but don't spend forever on it either.

**Wrap up.** You've used programming to invent new visual applications.

**Turn In.** Turn in two programs at the first due date, turn in the last two programs on the second due date.
